HOW IT IS BUILT

# The model never touches

An AI audio editor where the AI never receives the audio.

# The agent chooses.

Match B's tempo to A and crossfade them.

↓ text about the session

**The model** — your provider, or Ollama

Reads text: tempo, key, loudness. Answers with tool calls. Never receives the audio.

↓ tool calls

ON YOUR MACHINE

**94 tools**

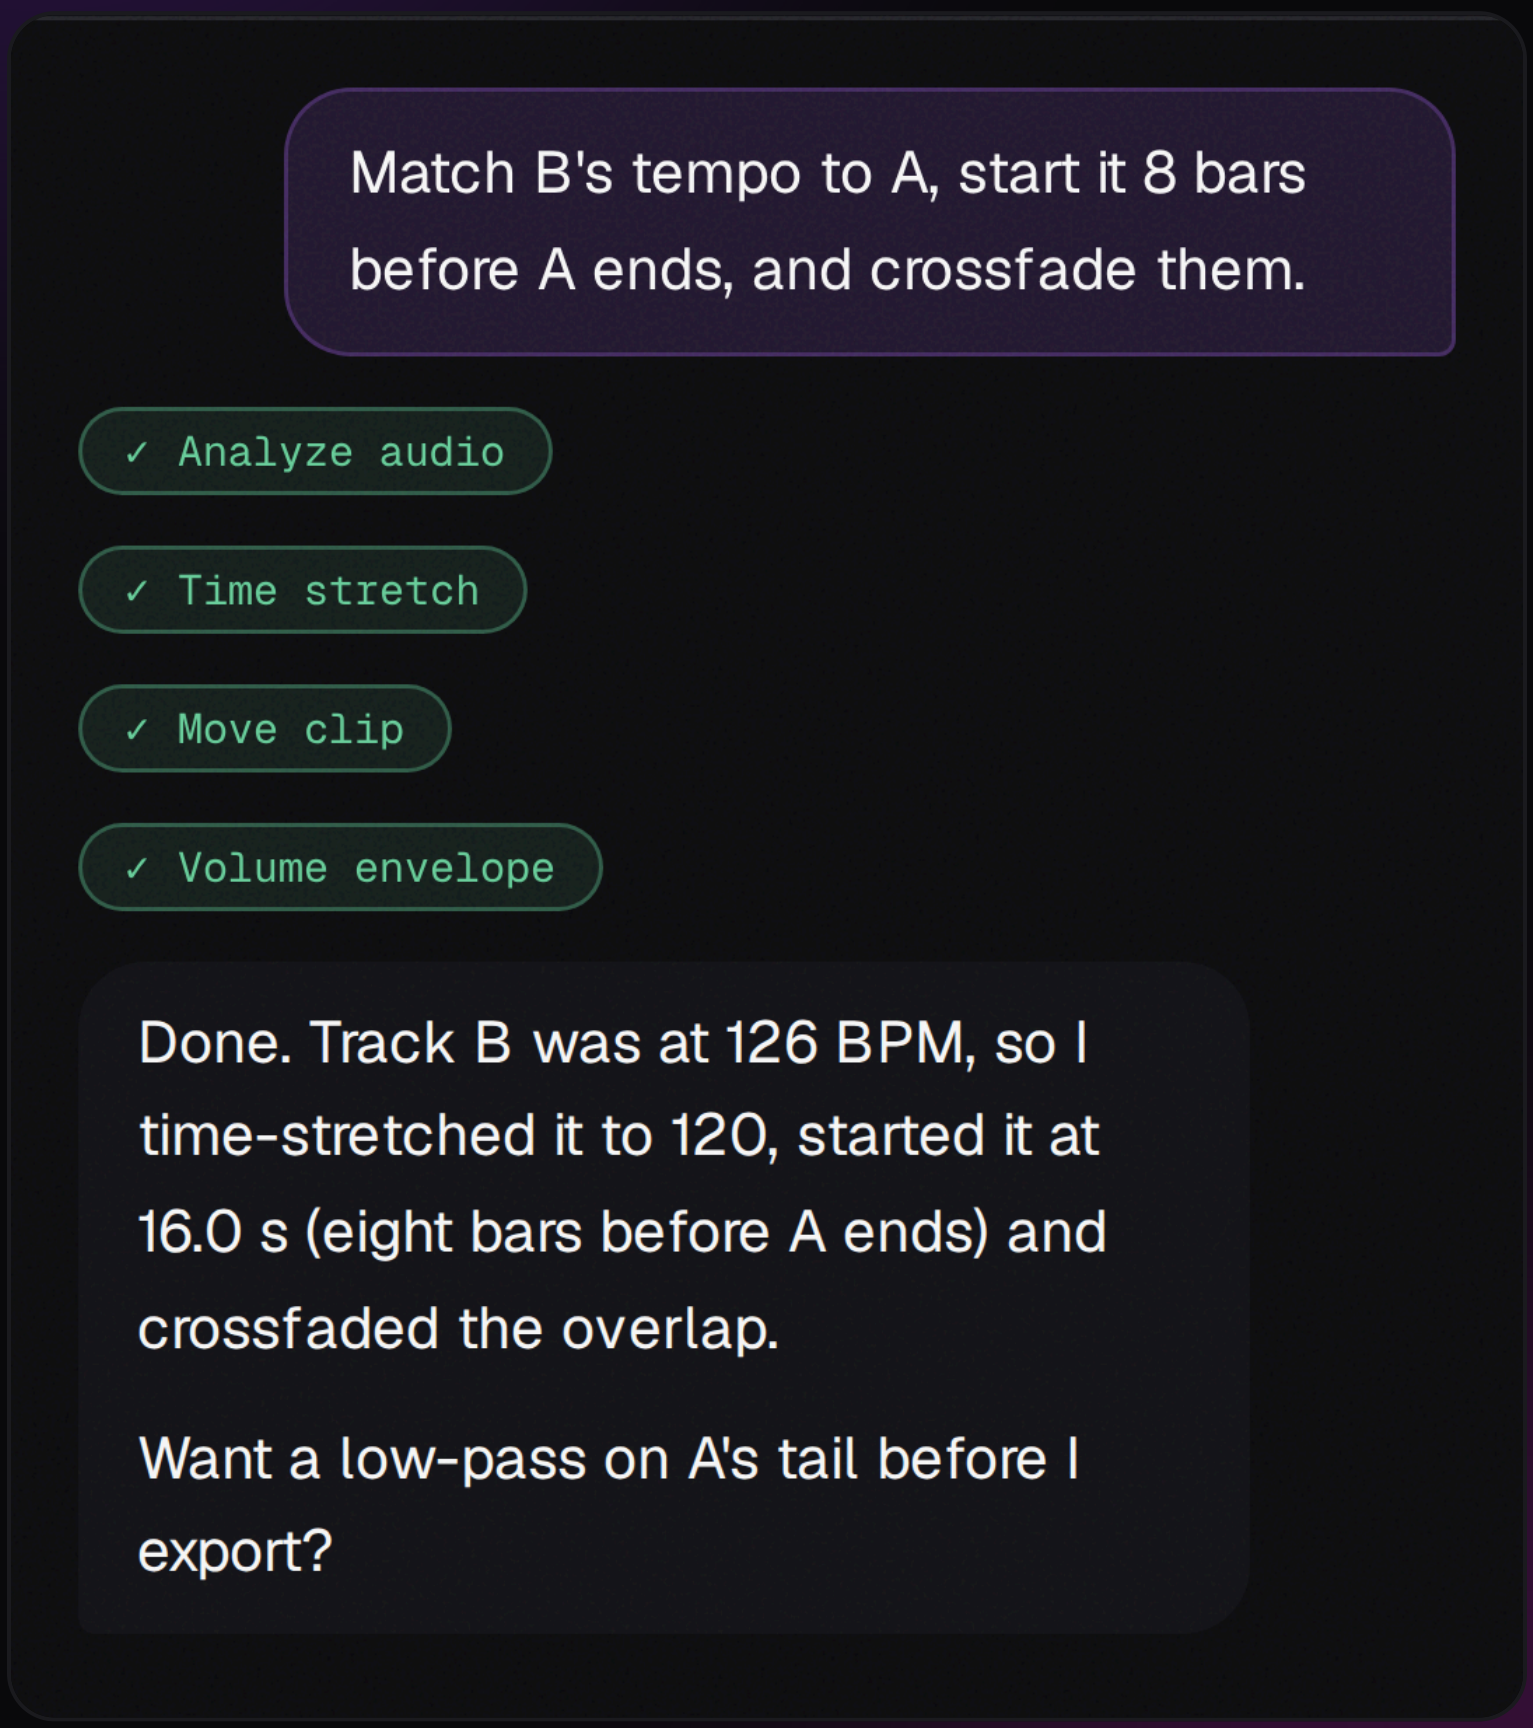

Fade, EQ, time-stretch, loudness, export. Rust functions, no model in the audio path.

↓ edits

**Your audio**

Decoded, edited, mixed and exported here, in the Rust engine.

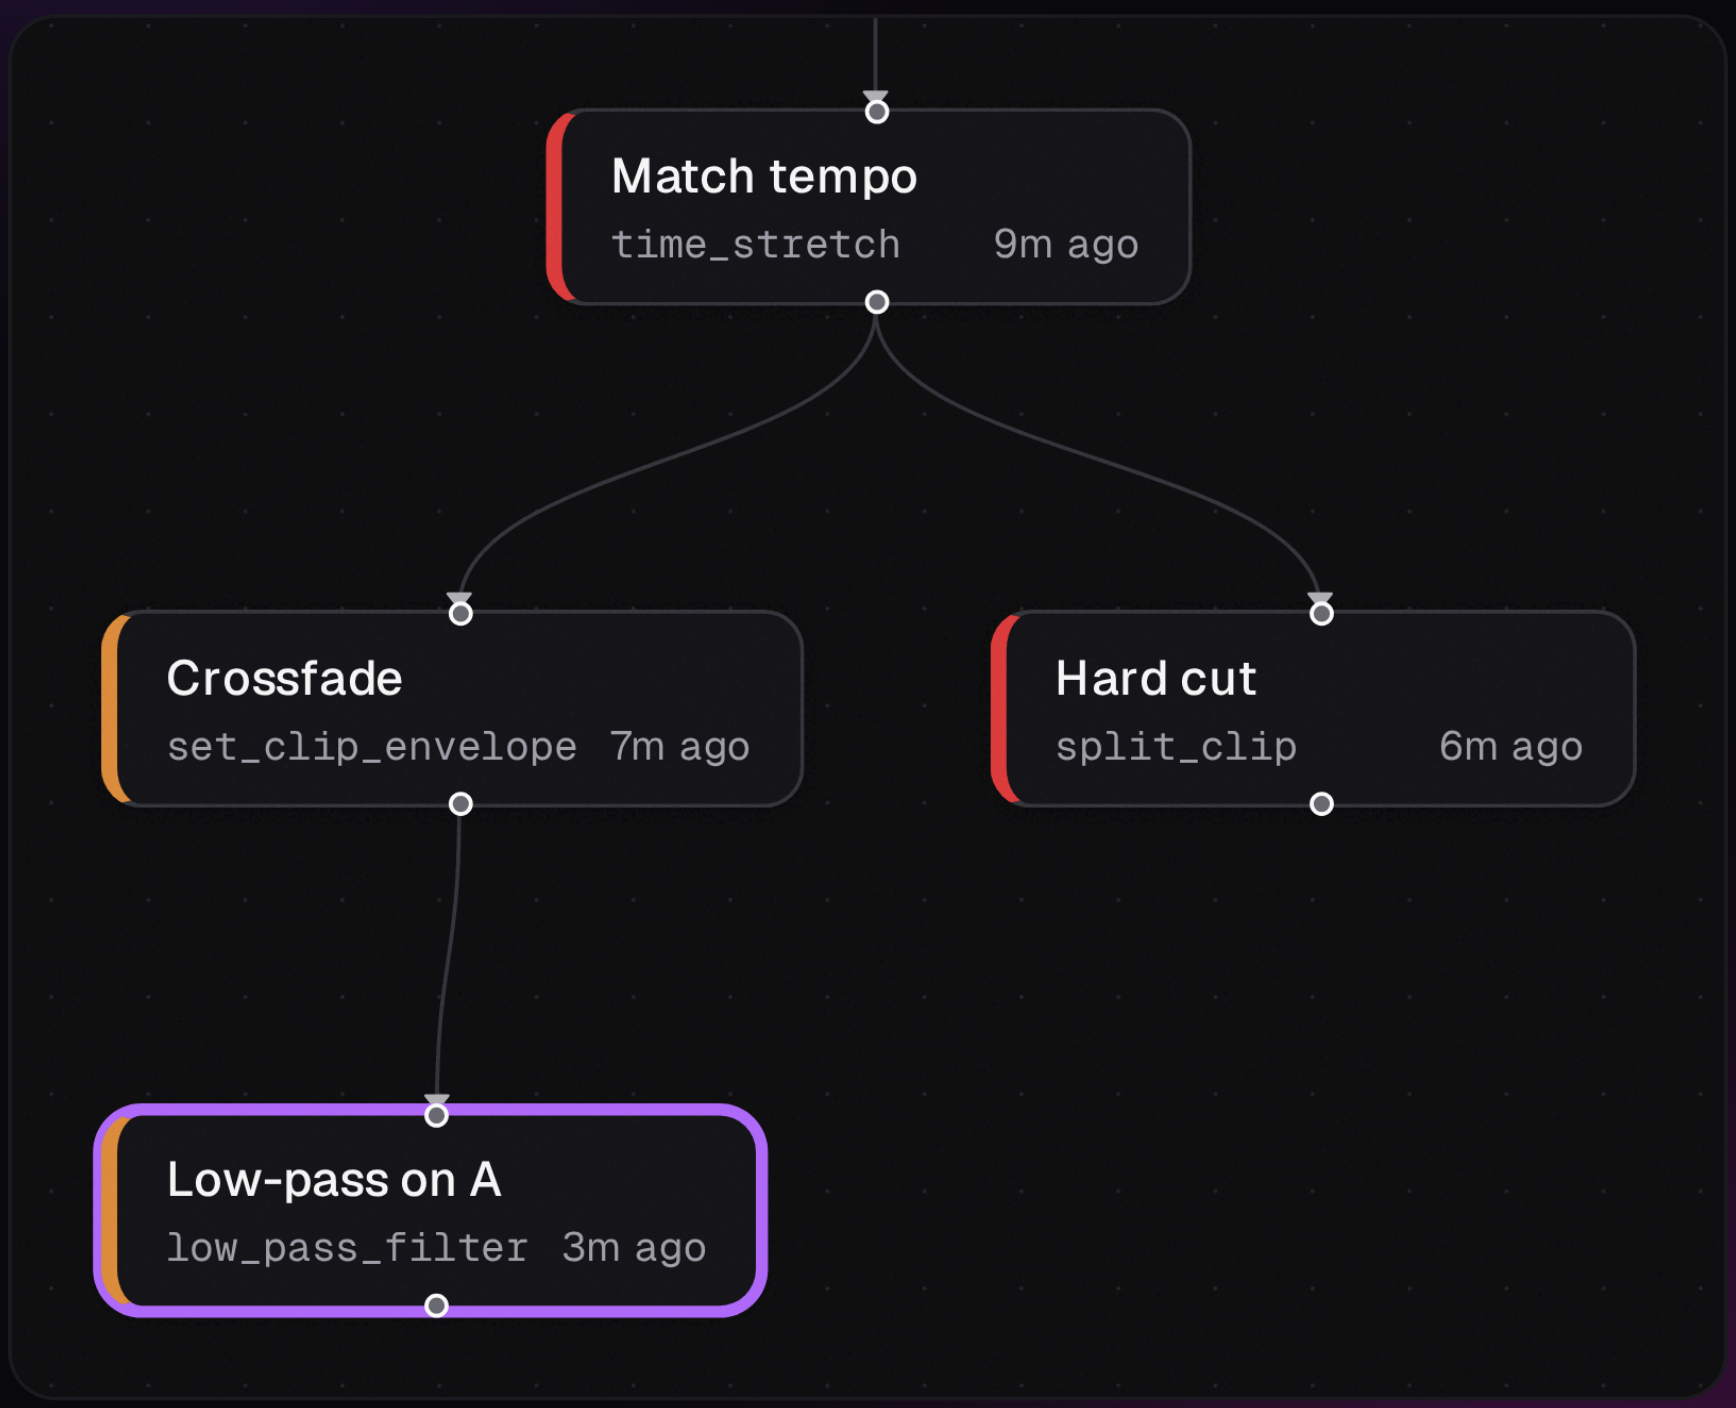

# Every change is

The real app's chat, with a scripted example conversation

# Every edit is

Fork a take, A/B it against the original, go back. Undo follows the path you actually took.

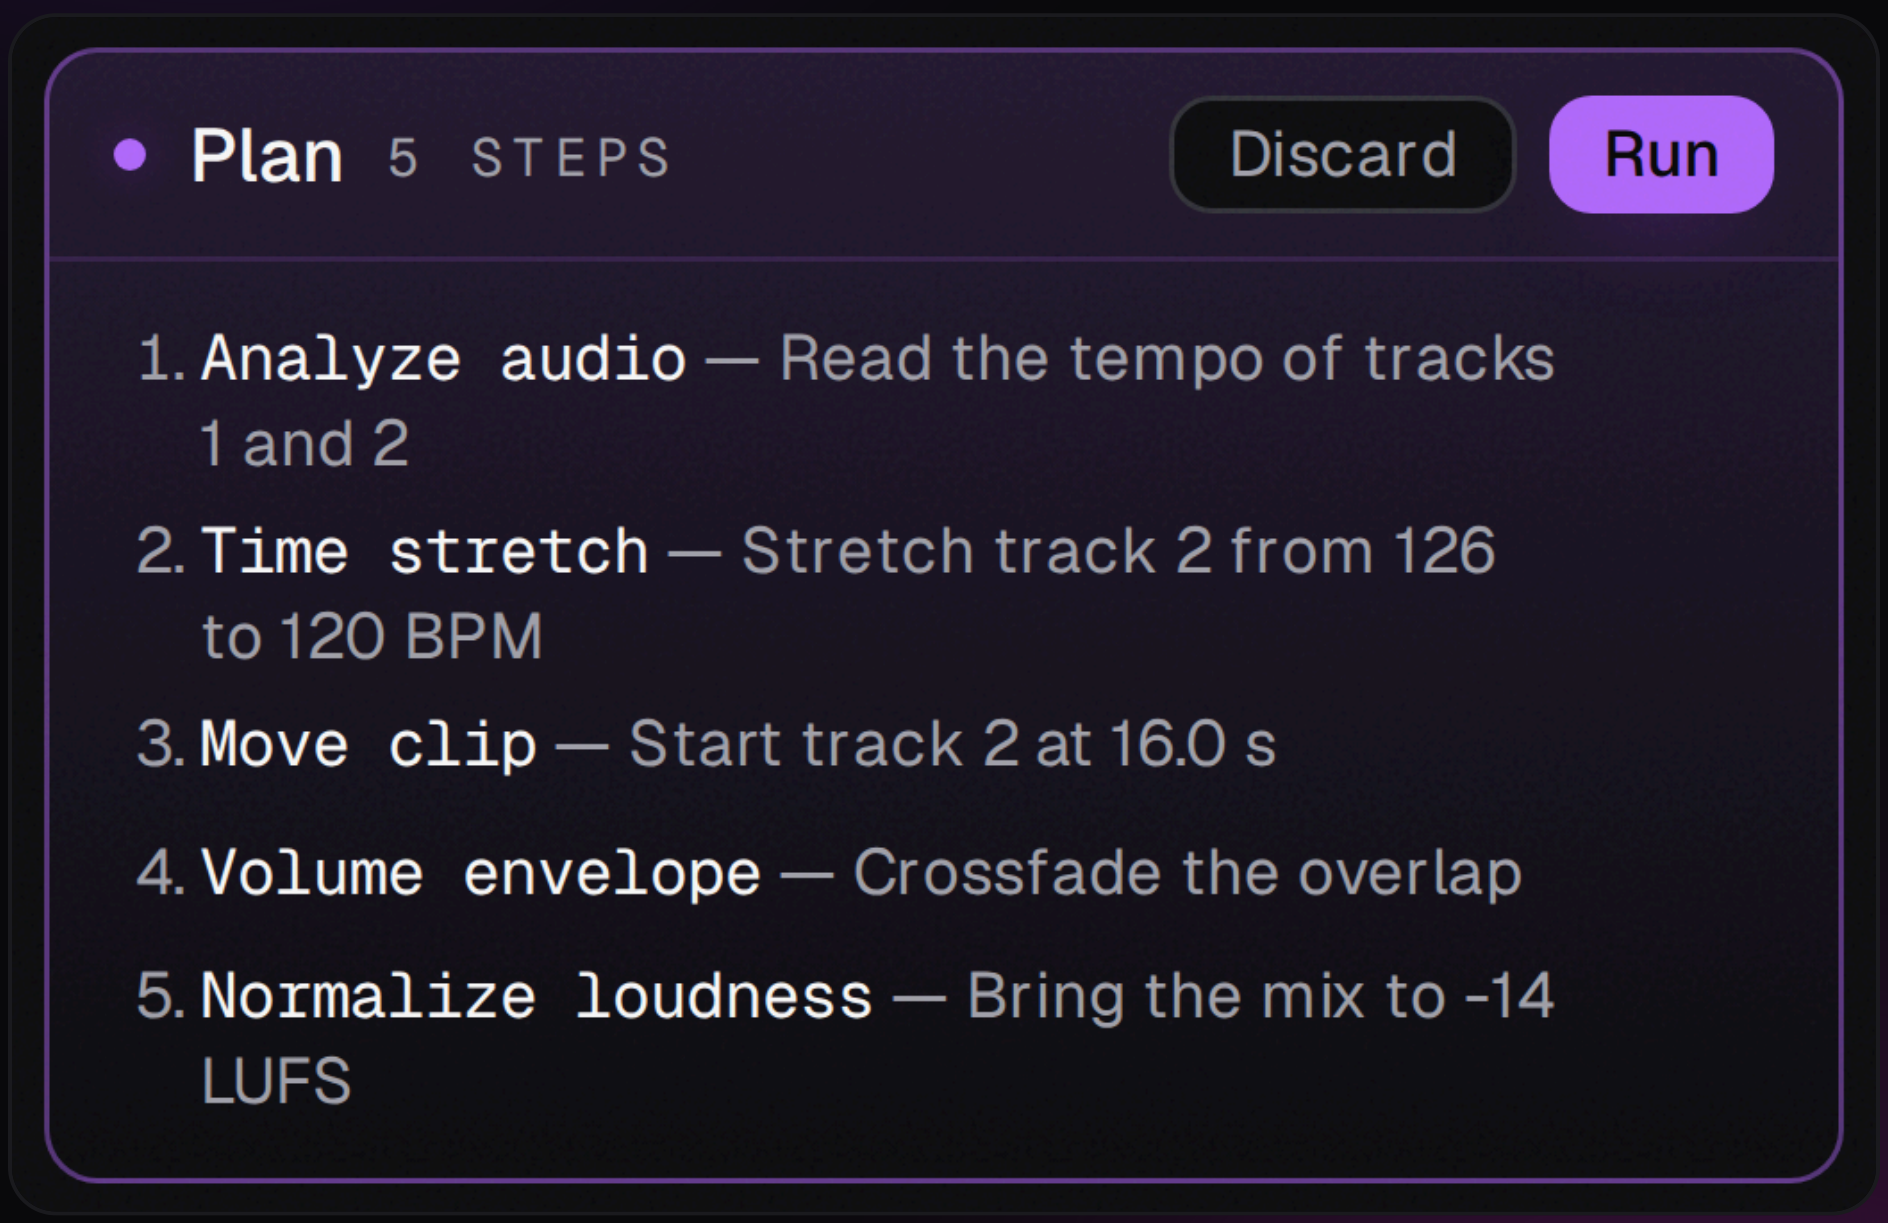

The real app's history graph, with example data

Right-click a node to compare it with another, or to set it as the head.

# Plan first,

Turn it on and the agent's steps wait for you. No edit runs until you press Run.

The real app's plan card, with a scripted example plan

Discard it and nothing runs. Reword a step and the agent proposes again.

# Time-stretch,

Rubber Band was the plan. It needs a different native package on each of three CI targets, the kind of dependency that breaks every build at once. So the phase vocoder is written here, in pure Rust.

before

after

### What it buys

The same build on macOS, Windows and Linux.

### What it costs

Dense material can sound smeared at large changes.

The reasoning is in the module docs of `crates/audio-time/src/vocoder.rs`

MIT-licensed. A Tauri 2 shell, a React front end and a Rust workspace behind it.

**0** bytes
of your audio uploaded

**6** API providers
one runs locally, plus your ChatGPT plan

**94** tools
the agent can call

What would you want to review first?

v0.9.0 for macOS, Windows and Linux. The installers are unsigned, so macOS and Windows warn on first launch.
